So this is going to be equal to 0. Because g is a solution. So if this is 0, c_1 times 0 is going to be equal to 0. So this expression up here is also equal to 0. Or another way to view it is that if g is a solution to this second order linear homogeneous differential

A trial solution of the form $y = A e^{mx}$ yields an “auxiliary equation”: $am^2 + bm + c = 0$, that will have two roots (m_1 and m_2). The general solution y of the o.d.e. is then constructed from the possible forms (y_1 and y_2 ... SECOND ORDER (homogeneous) ...

SECOND ORDER (homogeneous)

The first thing we want to learn about second-order homogeneous differential equations is how to find their general solutions. The formula we'll use for the general solution will depend on the kinds of roots we find for the differential equation.

The general solution of the homogeneous differential equation depends on the roots of the characteristic quadratic equation. There are the following options: Discriminant of the characteristic quadratic equation $(D > 0)$ Then the roots of the characteristic equations $(\{k_1\})$ and $(\{k_2\})$ are real and distinct.

There are two definitions of the term “homogeneous differential equation.” One definition calls a first-order equation of the form $y' + P(x)y = Q(x)$ homogeneous if M and N are both homogeneous functions of the same degree. The second definition — and the one which you'll see much more often—states that a differential equation (of any order) is homogeneous if once all the terms involving the unknown ...

In this section we discuss the solution to homogeneous, linear, second order differential equations, $ay'' + by' + c = 0$, in which the roots of the characteristic polynomial, $ar^2 + br + c = 0$, are complex roots. We will also derive from the complex roots the standard solution that is typically used in this case that will not involve complex numbers.
